

Figure 1. Detection functions fitted to the aerial survey data and distribution of perpendicular distances to harbour porpoise groups; showpoints indicate predicted value for each observation (conditional on its observed distance; Miller et al., 2019), stratified by good and moderate subjective conditions. a) for the Icelandic survey ($n=76$ sightings, of these 54 in good and 22 moderate conditions), b) for the Faroese survey ($n=39$ sightings, of these 29 in good and 10 moderate conditions).
